MEMS digital output motion sensor

low-power high performance 3-axes “DSC-XYZ” accelerometer

Key Features

- Supply voltage, 1.62V to 3.6V
- For 2x2x1.1 mm LGA-12 package
- User selectable range, $\pm 2g$, $\pm 4g$, $\pm 8g$, $\pm 16g$
- User selectable data output rate
- Digital I²C/SPI output interface
- 14 bit resolution
- Low power consumption
- 2 Programmable interrupt generators with independent function for motion detection
- Free-fall detection
- Embedded self-test function
- Factory programmable offset and sensitivity
- RoHS compliant

Applications

- User interface for mobile phone and PMP
- Display orientation
- Gesture recognition
- Active/inactive monitoring
- Free-fall detection
- Double/ Click recognition
- Power management
- Vibration monitoring
- Inclination and tilt sensing
- Pedometer

Product Overview

The da213 sensor is a low power high performance capacitive three-axis linear accelerometer developed by micro-machined technology. The device is available in a 2x2x1.1mm land grid array (LGA) and it is guaranteed to operate over an extended temperature range from -40°C to +85°C. The sensor element is fabricated by single crystal silicon with DRIE process and is protected by hermetically sealed silicon cap from the environment. The device features user selectable full scale of $\pm 2g$ / $\pm 4g$ / $\pm 8g$ / $\pm 16g$ measurement range with data output rate from 1Hz to 1 kHz with signal condition, temperature compensation, self-test, motion detection imbedded. The da213 has a self-test mode for user to check the functioning of the sensor and a power-down mode that makes it good for handset power management. Two independent and flexible interrupts provided greatly simplify the algorithm for various motion status detections. Standard I²C and SPI interfaces are used to communicate with the chip.

2 Mechanical and electrical specifications

2.1 Mechanical characteristics

V_{dd} = 2.5 V, T = 25 °C unless otherwise noted (a)

a. The product is factory calibrated at 2.5 V. The operational power supply range is from 1.62V to 3.6 V.

Table 2. Mechanical characteristic

Symbol	Parameter	Test conditions	Min	Type	Max	Unit
FS	Measurement range	FS bit set to 00		±2		g
		FS bit set to 01		±4		g
		FS bit set to 10		±8		g
		FS bit set to 11		±16		g
So	Sensitivity	FS bit set to 00		4096		LSB/g
		FS bit set to 01		2048		LSB/g
		FS bit set to 10		1024		LSB/g
		FS bit set to 11		512		LSB/g
TCS _o	Sensitivity change vs. temperature	FS bit set to 00		0.01		%/°C
Ty _{off}	Typical zero-g level offset accuracy			70		mg
Tc _{off}	Zero-g level change vs. temperature	Max delta from 25°C		±0.6		mg/°C
An	Acceleration noise density	FS bit set to 00, Normal Mode, ODR = 1000Hz		150	200	ug/sqrt(Hz)
Vst	Self-test output change	X: FS bit set to 00		400		mg
		Y: FS bit set to 00		400		mg
		Z: FS bit set to 00		400		mg
Top	Operation temperature range		-40		85	°C

2.2 Electrical characteristics

Vdd = 2.5 V, T = 25 °C unless otherwise noted

Table 3. Electrical characteristics

Symbol	Parameter	Test conditions	Min	Typ.	Max	Unit
Vdd	Supply voltage		1.62	2.5	3.6	V
Vdd_IO	I/O Pins supply voltage		1.62		3.6	V
Idd	current consumption in normal mode	Top=25°C, ODR=1kHz		180		uA
Idd_lp	current consumption in low power mode	Top=25°C, ODR=62.5Hz, BW=500Hz		40		uA
Idd_sm	current consumption in suspend mode	Top=25°C		1		uA
VIH	Digital high level input voltage	SPI&I2C	0.7*Vdd_IO			V
VIL	Digital low level input voltage	SPI&I2C			0.3*Vdd_IO	V
VOH	high level output voltage		0.9*Vdd_IO			V
VOL	Low level output voltage				0.1*Vdd_IO	V
BW	System bandwidth		1.95		500	Hz
ODR	Output data rate		1		1000	Hz
Wake-up time	twu	From stand-by		1		ms
Start-up time	tsu	From power off		3		ms
PSRR	Power Supply Rejection Rate	Top=25°C			20	mg/V

2.3 Absolute maximum ratings

Stresses above those listed as “absolute maximum ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device under these conditions is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

Table 4. Absolute maximum ratings

Parameter	Test conditions	Min	Max	Unit
Storage Temperature		-45	125	°C
Supply Voltage	Supply pins	-0.3	4.25	V
Supply Voltage	Logic pins	-0.3	Vdd_IO+0.3	V
ESD Rating	HMB,R=1.5k,C=100pF		±2	kV
Mechanical Shock	Duration<200us		10,000	g

Note: Supply voltage on any pin should never exceed 4.25V

This is a mechanical shock sensitive device, improper handling can cause permanent damages to the part.

This is an ESD sensitive device, improper handling can cause permanent damages to the part.

3 Communication interface

3.1 Communication interface Electrical specification

3.1.1 SPI Electrical specification

Table 5. Electrical specification of the SPI interface pins

Symbol	Parameter	Condition	Min	Max	Unit
f _{clk}	Clock frequency	Max load on SDIO or SDO = 25pF		10	MHz
t _{clk_l}	SLCK low pulse		20		
t _{clk_h}	SLCK high pulse		20		
T _{sd_i_setup}	SDI setup time		20		ns
T _{sd_i_hold}	SDI hold time		20		ns
T _{sd_o_od}	SDO/SDI output delay	Load = 25pF		30	ns
		Load = 250pF		40	ns
T _{csb_{setup}}	CSB setup time		20		ns
T _{csb_{hold}}	CSB hold time		40		ns

The figure below shows the definition of the SPI timing given in Table5:

Figure 3 SPI slave timing diagram

3.1.2 I2C Electrical specification

Table 6. Electrical specification of the I2C interface pins

Symbol	Parameter	Min	Max	Unit
fsc1	Clock frequency		400	kHz
tscl_l	SCL low pulse	1.3		us
tscl_h	SCL high pulse	0.6		us
Tsda_setup	SDA setup time	0.1		us
Tsda_hold	SDA hold time	0.0		us
tsusta	Setup Time for a repeated start condition	0.6		us
thdsta	Hold time for a start condition	0.6		us
tsusto	Setup Time for a stop condition	0.6		us
tbuf	Time before a new transmission can start	1.3		us

The figure below shows the definition of the I2C timing given in Table 6:

Figure 4 I2C Slave timing diagram

3.2 Digital interface operation

The da213 supports two serial digital interface protocols for communications as slave with a host device: SPI and I2C. The active interface is selected by the state of the pin PS, 0 selects SPI and 1 selects I2C. By default, SPI operates in 3-wire mode and it can be re-configured by writing 1 to bit ‘SDO_active’ to work in 4-wire mode. Both interfaces share the same pins. The mapping for each interface is given in the following table:

Table 7.Mapping of the interface pins

PIN name	I2C	SPI
SCL/SCLK	Serial clock	Serial clock
SDA/SDI	Serial Data	Data input (4-wire mode). Data input/output (3-wire mode)
SDO	Used to set LSB of I2C address	Data output (4-wire mode)
CSB	Unused	Chip select

3.2.1 SPI Operation

The falling edge of CSB, in conjunction with the rising edge of SCLK, determines the start of framing. Once the beginning of the frame has been determined, timing is straightforward. The first phase of the transfer is the instruction phase, which consists of 16 bits followed by data that can be of variable lengths in multiples of 8 bits. If the device is configured with CSB tied low, framing begins with the first rising edge of SCLK.

The instruction phase is the first 16 bits transmitted. As shown in Figure5, the instruction phase is divided into a number of bit fields.

Figure 5 Instruction Phase Bit Field

The first bit in the stream is the read/write indicator bit (R/W). When this bit is high, a read is being requested, otherwise indicates it is a write operation.

W1 and W0 represent the number of data bytes to transfer for either read or write (Table8). If the number of bytes to transfer is three or less (00, 01, or 10), CSB can stall high on byte boundaries. Stalling on a non-byte boundary terminates the communications cycle. If these bits are 11, data can be transferred until CSB transitions high. CSB is not allowed to stall during the streaming process.

The remaining 13 bits represent the starting address of the data sent. If more than one word is being sent, sequential addressing is used, starting with the one specified, and it either increments (LSB first) or decrements (MSB first) based

on the mode setting.

Table 8.W1 and W0 settings

W1:W0	Action	CSB stalling
00	1 byte of data can be transferred.	Optional
01	2 bytes of data can be transferred.	Optional
10	3 bytes of data can be transferred.	Optional
11	4 or more bytes of data can be transferred. CSB must be held low for entire sequence; otherwise, the cycle is terminated.	No

Data follows the instruction phase. The amount of data sent is determined by the word length (Bit W0 and Bit W1). This can be one or more bytes of data. All data is composed of 8-bit words.

Data can be sent in either MSB-first mode or LSB-first mode (by setting ‘LSB_first’ bit). On power up, MSB-first mode is the default. This can be changed by programming the configuration register. In MSB-first mode, the serial exchange starts with the highest-order bit and ends with the LSB. In LSB-first mode, the order is reversed. (Figure6)

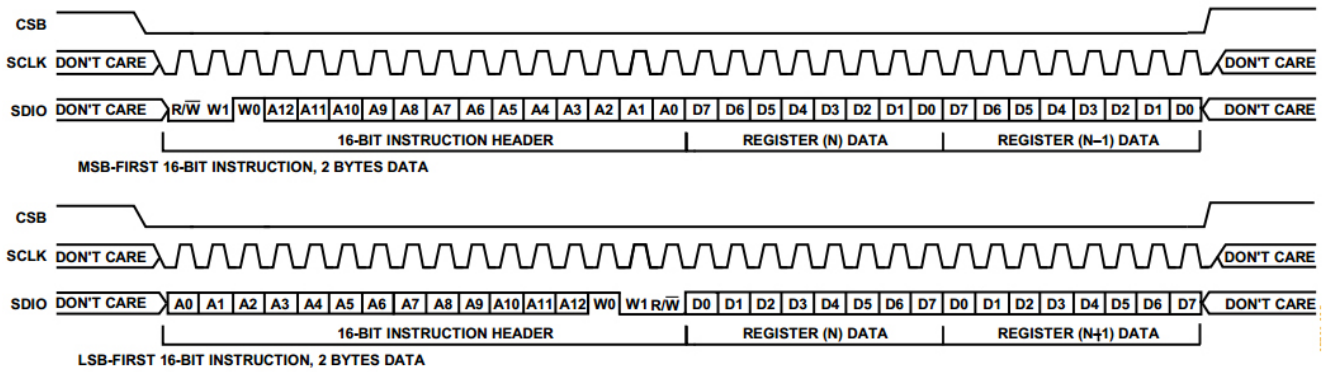

Figure 6 MSB First and LSB First Instruction and Data Phases

Register bit ‘SDO_active’ is responsible for activating SDO on devices. If this bit is cleared, then SDO is inactive and read data is routed to the SDIO pin. If this bit is set, read data is placed on the SDO pin. The default for this bit is low, making SDO inactive.

3.2.2 I2C Operation

I2C bus uses SCL and SDA as signal lines. Both lines are connected to VDDIO externally via pull-up resistors so that they are pulled high when the bus is free. The I2C device address of da213 is shown below. The LSB bit of the 7bits device address is configured via SA0pin.

Table 9.I2C Address

SAD6	SAD5	SAD4	SAD3	SAD2	SAD1	SAD0	W/R
0	1	0	0	1	1	SA0	0/1

Table 10.SAD+Read/Write patterns

Command	SAD[6:1]	SAD[0]=SA0	R/W	SAD+R/W
Read	010011	0	1	01001101(4dh)
Write	010011	0	0	01001100(4ch)
Read	010011	1	1	01001111(4fh)
Write	010011	1	0	01001110(4eh)

The I2C interface protocol has special bus signal conditions. Start (S), stop (P) and binary data conditions are shown below. At start condition, SCL is high and SDA has a falling edge. Then the slave address is sent. After the 7 address bits, the direction control bit R/W selects the read or write operation. When a slave device recognizes that it is being addressed, it should acknowledge by pulling SDA low in the ninth SCL (ACK) cycle.

At stop condition, SCL is also high, but SDA has a rising edge. Data must be held stable at SDA when SCL is high. Data can change value at SDA only when SCL is low.

4 Terminology and functionality

4.1 Terminology

4.1.1 Sensitivity

Sensitivity describes the gain of the sensor and can be determined e.g. by applying 1 g acceleration to it. As the sensor can measure DC accelerations this can be done easily by pointing the axis of interest towards the center of the earth, noting the output value, rotating the sensor by 180 degrees (pointing to the sky) and noting the output value again. By doing so, ± 1 g acceleration is applied to the sensor. Subtract the larger output value from the smaller one, and dividing the result by 2, leads to the actual sensitivity of the sensor. This value changes very little over temperature and also time. The sensitivity tolerance describes the range of sensitivities of a large population of sensors.

4.1.2 Zero-g level

Zero-g level offset (TyOff) describes the deviation of an actual output signal from the ideal output signal if no acceleration is present. A sensor in a steady state on a horizontal surface measure 0 g in X axis and 0 g in Y axis whereas the Z axis measure 1 g. The output is ideally in the middle of the dynamic range of the sensor (content of output data registers are 00h, data expressed as 2's complement number). A deviation from ideal value in this case is called Zero-g offset. Offset is to some extent a result of stress to MEMS sensor and therefore the offset can slightly change after mounting the sensor onto a printed circuit board or exposing it to extensive mechanical stress. Offset changes little over temperature; see "Zero-g level change vs. temperature". The Zero-g level tolerance (TyOff) describes the standard deviation of the range of Zero-g levels of a population of sensors.

4.2 Functionality

4.2.1 Power mode

The da213 has three different power modes. Besides normal mode, which represents the fully operational state of the device, there are two special energy saving modes: low-power mode and suspend mode.

Figure 8 power mode

In normal mode, all parts of the electronic circuit are held powered-up and data acquisition is performed continuously.

In suspend mode, the whole analog part, including the oscillator, Ana LDO, Dig LDO and Drive Buffer are all powered down, no data acquisition is performed and the only supported operation is to read/write the registers. Suspend mode is entered by writing '11' or '10' to the (0x11) 'pwr_mode' bits.

In low power mode, the device is periodically switching between a sleep phase and a wake-up phase. The wake-up phase essentially corresponding to operation in normal mode with complete power-up of the circuitry. During the sleep phase the analog part except the oscillator is powered down.

During the wake-up phase, if a enabled interrupt is detected, the device stays in the wake-up phase as long as the interrupt condition endures (non-latched interrupt), or until the latch time expires (temporary interrupt), or until the interrupt is reset (latched interrupt). If no interrupt detected, the device enters the sleep phase.

4.2.2 Sensor data

The width of acceleration data is 14bits given in two's complement representation. The 14bits for each axis are split into an MSB part (one byte containing bits 13 to 6) and an LSB lower part (one byte containing bits 5 to 0)

4.2.3 Self-test

This feature permits to check the sensor functionality by applying electrostatic forces to the sensor core instead of external accelerations. By actually deflecting the seismic mass, the entire signal path of the sensor can be tested. Activating the self-test results in a static offset of the acceleration data; any external acceleration or gravitational force

applied to the sensor during active self-test will be observed in the output as a superposition of both acceleration and self-test signal.

The self-test is activated individually for each axis by writing 1 to the (0x32) 'self_test_en' bit. It is possible to control the direction of the deflection though bit 'self_test_sign' for each axis. The excitation occurs in positive (negative) direction if 'self_test_sign' = '0b' ('1b').

In order to ensure a proper interpretation of the self-test signal it is recommended to perform the self-test for both directions and then to calculate the difference of the resulting acceleration values. Table15 show the difference for each axis.

Table 15. Self-test difference values

	X-axis signal	Y-axis signal	Z-axis signal
Resulting difference value	+0.4g	+0.4g	+0.4g

4.2.4 Factory calibration

The IC is factory calibrated for sensitivity (S_0) and Zero-g level ($TyOff$). The trimming values are stored inside the chip's nonvolatile memory. The trimming parameters are loaded to registers while da213 reset (POR or software reset). This allows using the device without further calibration.

4.3 Interrupt controller

Interrupt engines are integrated in the da213. Each interrupt can be independently enabled and configured. If the condition of an enabled interrupt is fulfilled, the corresponding status bit is set to 1 and the selected interrupt pin is activated. There are two interrupt pins, INT1 and INT2; interrupts can be freely mapped to any of these two pins. The pin state is a logic 'or' combination of all mapped interrupts.

4.3.1 General features

An interrupt is cleared depending on the selected interrupt mode, which is common to all interrupts. There are three different interrupt modes: non-latched, latched and temporary. The mode is selected by the 'latch_int' bits according to table16.

Table 16. Interrupt mode selection

latch_int	Interrupt mode
0000	non-latched
0001	temporary latched 250ms
0010	temporary latched 500ms
0011	temporary latched 1s
0100	temporary latched 2s
0101	temporary latched 4s

0110	temporary latched 8s
0111	latched
1000	non-latched
1001	temporary latched 1ms
1010	temporary latched 1ms
1011	temporary latched 2ms
1100	temporary latched 25ms
1101	temporary latched 50ms
1110	temporary latched 100ms
1111	latched

An interrupt is generated if its activation condition is met. It can't be cleared as long as the activation condition is fulfilled. In the non-latched mode the interrupt status bit and the selected pin (INT1 or INT2) are cleared as soon as the activation condition is no more valid. Exceptions to this behavior are the new data and orientation, which are automatically reset after a fixed time.

In the latched mode an asserted interrupt status and the selected pin are cleared by writing 1 to (0x21) 'reset_int' bit. If the activation condition still holds when it is cleared, the interrupt status is asserted again with the next change of the acceleration registers.

In the temporary mode an asserted interrupt and selected pin are cleared after a defined period of time. The behavior of the different interrupt modes is shown in figure 9.

Figure 9 Interrupt mode

4.3.2 Mapping

The mapping of interrupts to the interrupt pins is done by registers 'INT_MAP_x' (0x19 0x1a and 0x1b), setting *int1_inttype* (e.g. *int1_freefall*) to 1 can map this type of interrupt to INT1 pin and setting *int2_inttyp* to 1 can map this type interrupt to INT2 pin.

4.3.3 Electrical behavior (INT1/INT2 to open-drive or push-pull)

Both interrupt pins can be configured to show desired electrical behavior. The active level for each pin is set by register bit `int1_lvl` (`int2_lvl`), if `int1_lvl` (`int2_lvl`) = 0 (1), then the pin INT1 (INT2) is 0 (1) active.

Also the electric type of the interrupt pin can be selected. By setting `int1_od` (`int2_od`) = 1 (0), the interrupt pin output type can be set to be open-drive (push-pull).

4.3.4 New data interrupt

This interrupt serves for synchronous reading of acceleration data. It is generated after an acceleration data was calculated. The interrupt is cleared automatically before the next acceleration data is ready.

4.3.5 Active detection

Active detection uses the slope between successive acceleration signals to detect changes in motion. An interrupt is generated when the slope (absolute value of acceleration difference) exceeds a preset threshold. The threshold is set with the value of register 'active_th' with the LSB corresponding to 16 LSB of acceleration data, that is 3.9mg in 2g-range, 7.8mg in 4g-range, 15.6mg in 8g-range and 31.3mg in 16g-range. And the maximum value is 1g in 2g-range, 2g in 4g-range, 4g in 8g-range and 8g in 16g-range.

The time difference between the successive acceleration signals depends is fixed to 1ms.

Active detection can be enabled (disabled) for each axis separately by writing '1' to bits 'active_int_en_x/y/z'. The active interrupt is generated if the slope of any of the enabled axes exceeds the threshold for [`active_dur`+1] consecutive times. As soon as the slopes of all enabled axes fall below this threshold for [`active_dur`+1] consecutive times, the interrupt is cleared unless the interrupt signal is latched.

The interrupt status is stored in the (0x09) 'active_int' bit. The (0x0b) bit 'active_first_x/y/z' records which axis triggered the active interrupt first and the sign of this acceleration data that triggered the interrupt is recorded in the (0x0b) bit 'active_sign'.

4.3.6 Tap detection

Tap detection has a functional similarity with a common laptop touch-pad or clicking keys of a computer mouse. A tap event is detected if a pre-defined pattern of the acceleration slope is fulfilled at least for one axis. Two different tap events are distinguished: A single tap is a single event within a certain time, followed by a certain quiet time. A double tap consist a first such event followed by a second event within a defined time.

Single tap interrupt is enabled by writing 1 to the (0x16) 's_tap_int_en' bit and double tap interrupt is enabled by writing 1 to the (0x16) 'd_tap_int_en' bit. The status of the single tap interrupt is stored in the (0x09) 's_tap_int' bit and the status of the double tap interrupt is stored in the (0x09) 'd_tap_int' bit.

The slope threshold for detecting a tap event is set by the (0x2b) "tap_th" bits with the LSB corresponding to 256LSB

of acceleration data that is 62.5mg in 2g-range, 125mg in 4g-range, 250mg in 8g-range, 500mg in 16g-range. And the maximum value equals to the full scale in each range.

In figure10 the meaning of different timing parameter is visualized.

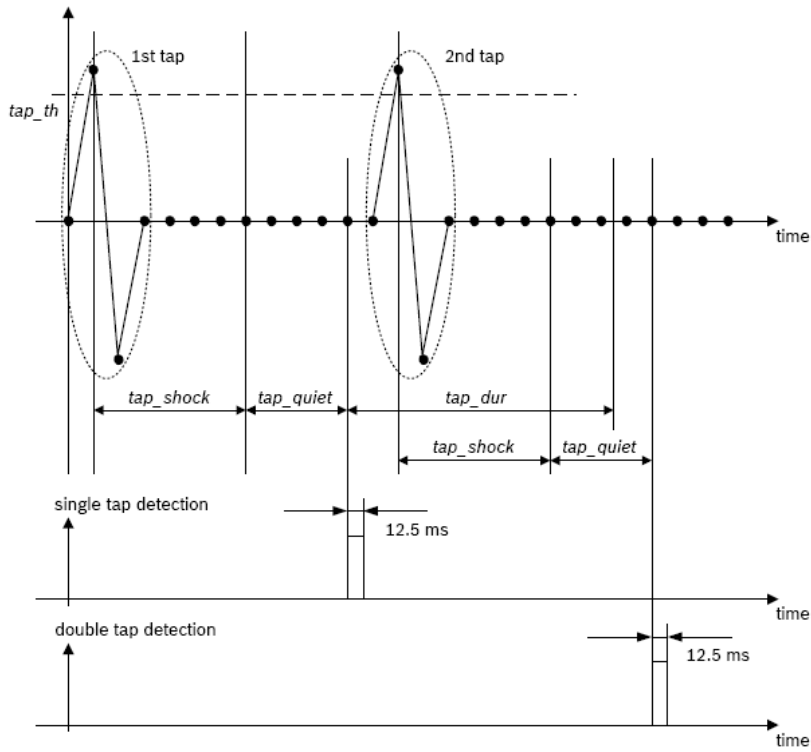

Figure 10 Timing of tap detection

The parameter 'tap_shock' and 'tap_quiet' apply to both single and double tap detection, while 'tap_dur' applies to double detection only. Within the duration of 'tap_shock' any slope exceeding 'tap_th' after the first event is ignored, within the duration of 'tap_quiet' there must be no slope exceeding 'tap_th', otherwise the first event will be cancelled. A single tap is detected and the single tap interrupt is generated after the combination durations of 'tap_shock' and 'tap_quiet', if the corresponding slope conditions are fulfilled. The interrupt is cleared after a delay of 12.5ms in non-latched mode.

A double tap is detected and the double tap interrupt is generated if an event fulfilling the conditions for a single tap occurs within the set duration in 'tap_dur' after the completion of the first tap event. The interrupt is cleared after a delay in non-latched mode.

The sign of the slope of the first tap which triggered the interrupt is stored in the (0x0b) 'tap_sign' bit (0 means positive, 1 means negative). The axis which triggered the interrupt is indicated by the (0x0b) 'tap_first_x/y/z' bit.

Note: 'tap_shock' 'tap_quiet' 'tap_dur' 'tap_th' can be set by modifying register 0x2a and 0x2b

4.3.7 Orientation recognition

The orientation recognition feature informs on an orientation change of sensor with respect to the gravitation field vector ‘g’. The measured acceleration vector components with respect to the gravitation field are defined as shown in figure 11.

Figure 11 Definition of vector components

Therefore, the magnitudes of the acceleration vectors are calculated as follows:

$$acc_x = 1g \cdot \sin \theta \cdot \cos \varphi$$

$$acc_y = -1g \cdot \sin \theta \cdot \sin \varphi$$

$$acc_z = 1g \cdot \cos \theta$$

Depending on the magnitudes of the acceleration vectors the orientation of the device in the space is determined and stored in the (0x09) ‘orient_int’ bit. There are three orientation calculation modes with different thresholds for switching between different orientations: symmetrical, high-asymmetrical and low-asymmetrical. The mode is selected by setting the (0x2c) ‘orient_mode’ bit. For each orientation mode, the ‘orient’ bits have a different meaning as show in table 17 to table 18.

Table 17.meaning of ‘orient’ bits in symmetric mode

orient	Name	Angle	Condition
X00	Portrait upright	$315^\circ < \varphi < 45^\circ$	$ acc_y < acc_x - 'hyst' \ \&acc_x \geq 0$
X01	Portrait upside down	$135^\circ < \varphi < 225^\circ$	$ acc_y < acc_x - 'hyst' \ \&acc_x < 0$
X10	Landscape left	$45^\circ < \varphi < 135^\circ$	$ acc_y \geq acc_x + 'hyst' \ \& \ acc_y < 0$
X11	Landscape right	$225^\circ < \varphi < 315^\circ$	$ acc_y \geq acc_x + 'hyst' \ \& \ acc_y \geq 0$

Table 18.meaning of ‘orient’ bits in high-asymmetric mode

Orient	Name	Angle	Condition
X00	Portrait upright	$297^\circ < \varphi < 63^\circ$	$ acc_y < 2* acc_x - 'hyst' \ \&acc_x \geq 0$
X01	Portrait upside down	$117^\circ < \varphi < 243^\circ$	$ acc_y < 2* acc_x - 'hyst' \ \&acc_x < 0$
X10	Landscape left	$63^\circ < \varphi < 117^\circ$	$ acc_y \geq 2* acc_x + 'hyst' \ \& \ acc_y < 0$
X11	Landscape right	$243^\circ < \varphi < 297^\circ$	$ acc_y \geq 2* acc_x + 'hyst' \ \& \ acc_y \geq 0$

Table 19.meaning of ‘orient’ bits in low-asymmetric mode

Orient	Name	Angle	Condition
X00	Portrait upright	$333^\circ < \varphi < 27^\circ$	$ \text{acc}_y < 0.5 * \text{acc}_x - \text{'hyst'}$ & $\text{acc}_x \geq 0$
X01	Portrait upside down	$153^\circ < \varphi < 207^\circ$	$ \text{acc}_y < 0.5 * \text{acc}_x - \text{'hyst'}$ & $\text{acc}_x < 0$
X10	Landscape left	$27^\circ < \varphi < 153^\circ$	$ \text{acc}_y \geq 0.5 * \text{acc}_x + \text{'hyst'}$ & $\text{acc}_y < 0$
X11	Landscape right	$207^\circ < \varphi < 333^\circ$	$ \text{acc}_y \geq 0.5 * \text{acc}_x + \text{'hyst'}$ & $\text{acc}_y \geq 0$

In the preceding tables, the parameter ‘hyst’ stands for a hysteresis which can be selected by the (0x2c) ‘orient_hyst’ bit. 1LSB of ‘orient_hyst’ always corresponds to 62.5mg in any g-range. The MSB of ‘orient’ bits contains information about the direction of the z-axis. It is set to 0(1) if $\text{acc}_z \geq 0$ ($\text{acc}_z < 0$). The hysteresis for z axis is fixed to 0.2g.

The orient interrupt is enabled by writing the (0x16) ‘orient_int_en’ bit. The interrupt is generated if the value of ‘orient’ has changed. It is automatically cleared after one stable period of the orient value in non-latched mode. In temporary latched or latched mode, the orient value is kept fixed as long as the interrupt persists. After cleaning the interrupt, the ‘orient’ will updated with the next following value change.

The change of the ‘orient’ value and the generation of the interrupt can be blocked according to conditions selected by setting the value of the (0x2c) ‘orient_block’ bit as described by table20.

Table 20.blocking conditions for orientation recognition

orient_block	Conditions
00b	No blocking
01b	Z blocking
10b	Z blocking or acceleration slope in any axis $> 0.2g$
11b	No blocking

The Z blocking is defined by the following inequality:

$$|\text{acc}_z| > z_blocking$$

The parameter z_blocking of the above given equation stands for the contents of the (0x2d) ‘z_blocking’ bit. Hereby it is possible to define a blocking value between 0g and 0.9375g with an LSB = 0.0625g.

4.3.8 Freefall interrupt

This interrupt is based on the comparison of acceleration data against a low-g threshold. The interrupt is enabled by writing 1 to the (0x17) ‘freefall_int_en’ bit. There are two modes available: single mode and sum mode. In single mode the acceleration of each axis is compared with the threshold. In sum mode, the sum of absolute values of all accelerations $|\text{acc}_x| + |\text{acc}_y| + |\text{acc}_z|$ is compared with the threshold. The mode is selected by the (0x24) ‘freefall_mode’ bit. The free fall threshold is set through the (0x23) ‘freefall_th’ bits with 1 LSB corresponding to an acceleration of 7.81mg. A hysteresis can be selected by setting the (0x24) ‘freefall_hy’ bits with 1 LSB corresponding to 125mg.

The freefall interrupt is generated if the absolute values of the acceleration of all axes or their sum are lower than the threshold for at least the time defined by the (0x22) ‘freefall_dur’ bits. The interrupt is reset if the absolute value of at

least one axis or the sum is higher than the threshold plus the hysteresis for at least one data acquisition. The interrupt status is stored in the (0x09) 'freefall_int' bit.

5 Application hints

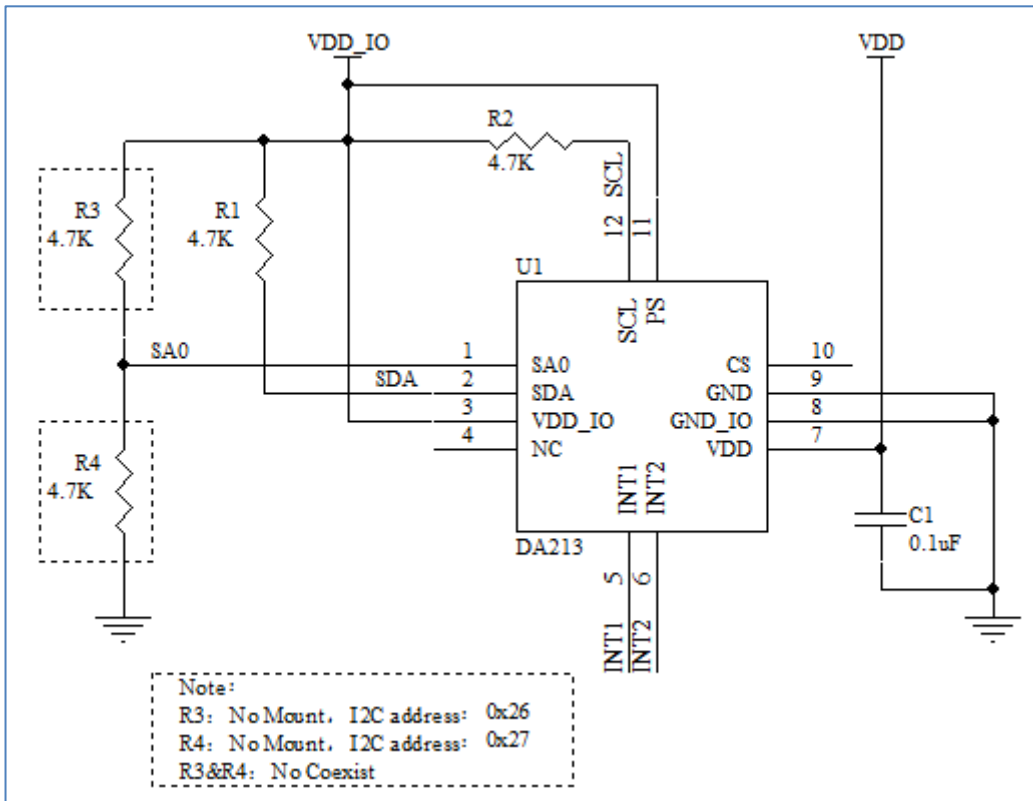

Figure 12 da213 I2C electrical connection

The device core is supplied through Vdd line while the I/O pads are supplied through Vdd_IO line. Power supply decoupling capacitors (100 nF ceramic) should be placed as near as possible to the pin 7 and pin 3 of the device (common design practice).

The functionality of the device and the measured acceleration data is selectable and accessible through the I2C or SPI interfaces. When using the I2C, PS must be tied high. The functions, the threshold and the timing of the two interrupt pins (INT1 and INT2) can be completely programmed by the user through the I2C/SPI interface.

6 Register mapping

The table given below provides a listing of the 8 bit registers embedded in the device and the related addresses:

9 Reliability

The qualification condition of MiraMEMS's products is based on the stress test qualification for integrated circuits, JEDEC JESD47H.01 Standard. The test summary is listed below.

Table 99. Accelerated Life Tests

Test	Condition	Qty/lot	Lot	Acc/Rej	Result
High Temperature Storage (HTS)*	150C, 1000hrs JEDEC JESD22-A103D Condition A	77	3	0/1	PASS
High Temperature Operating Life Test (HTOL)*	125C, 1000hrs, 3.63V biased JEDEC JESD22-A108D	77	3	0/1	PASS
Highly Accelerated Stress Test (uHAST)*	130C/85%, 96hrs JEDEC JESD22-A118A Condition A	77	3	0/1	PASS

*Tests are preceded by MSL3 preconditioning in accordance with JEDEC JESD22-A113F

Table 100. Component Level Tests

Test	Condition	Qty/lot	Lot	Acc/Rej	Result
Preconditioning(MSL3)	24hrs HTSL (125C) ->192Hrs WHTSL (30C/60%RH) + 3x PbFree Reflow, 260C max JEDEC JESD22-A113F	77	3	0/1	PASS
Temperature Cycle*	-40C~85C (air to air) 500 cycles JEDEC JESD22-A104D Condition N	77	3	0/1	PASS
Shock Test	10000G/0.2ms, X/Y/Z 5 time/ direction JEDEC JESD22-B104C	10	3	0/1	PASS
Vibration Test	sweep 20-2000Hz, 4 times/direction JEDEC JESD22-B103B Condition 1 60Hz_32h/direction	10	2	0/1	PASS
ESD Susceptibility	2000V (HBM) JEDEC JS-001-2012	6	1	0/1	PASS
	200V (MM) JEDEC JESD22-A115C	6	1	0/1	PASS
	500V (CDM) JEDEC JESD22-C101E	6	1	0/1	PASS
Latch-up	>+/-2Vcc, max >+/-2Icc, max JEDEC JESD-78D	6	1	0/1	PASS

*Tests are preceded by MSL3 preconditioning in accordance with JEDEC JESD22-A113F

10 Revision history

Table 101. Document revision history

Date	Revision	Changes
10-Sep-2013	0.1	Initial release
10-Feb-2014	1.0	Update Electrical characteristics
23-May-2014	1.1	Add tap & reel info
29-Oct.-2014	1.2	Add a reliability section
19-Dec.-2014	1.3	Modify the package outline dimensions
