# LVDS CLOCK MULTIPLIER FOR VIDEO APPLICATIONS

# ICS874S336

## General Description

The ICS874S336 is a high performance, 1-to-1, Differential-to-LVDS Clock Multiplier and is a member of the HiPerClocksS™ family of High Performance Clock Solutions from IDT. The CLK/nCLK input pair can accept most standard

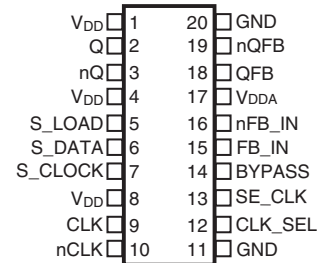

differential input levels. The ICS874S336 has a fully integrated PLL along with frequency configurable outputs. An external feedback output regenerates clocks with “zero delay”.

The ICS874S336 has multiple divide combinations designed to work with the most common video rates used in professional video systems.

## Features

- One LVDS differential output pair, plus one LVDS feedback output pair
- One differential clock input pair CLK/nCLK can accept the following differential input levels: LVPECL, LVDS, LVHSTL, HCSSL, SSTL
- Input Frequency Range: 14MHz to 17MHz
- Maximum Output Frequency: 204MHz
- VCO range: 1.2GHz – 2GHz
- Cycle-to-cycle jitter: TBD
- 3.3V operating supply voltage
- Low PLL bandwidth allows for better jitter attenuation
- 0°C to 70°C ambient operating temperature
- Available in both standard (RoHS 5) and lead-free (RoHS 6) packages

## Pin Assignment

The Preliminary Information presented herein represents a product in pre-production. The noted characteristics are based on initial product characterization and/or qualification. Integrated Device Technology, Incorporated (IDT) reserves the right to change any circuitry or specifications without notice.

## Block Diagram

## Functional Description

The ICS874S336 features a fully integrated PLL and therefore requires no external components for setting the loop bandwidth. The VCO of the PLL operates over a range of 1.2GHz to 2GHz. The output of the M divider is also applied to the phase detector.

The phase detector and the M divider force the VCO output frequency to be M times the reference frequency by adjusting the VCO control voltage. Note that for some values of M (either too high or too low), the PLL will not achieve lock. The output of the VCO is scaled by a divider prior to being sent to each of the LVPECL output buffers. The divider provides a 50% output duty cycle.

The relationship between the VCO frequency, the input frequency and the M divider is defined as follows:

$$f_{VCO} = \frac{f_{IN} \times M \times N}{P} \times 2$$

The M, N, and P values used to obtain the proper video

frequencies are found in Table 3B, *Programmable VCO Frequency Function Table*. The actual data bits can be found in Tables 3C, 3D and 3E.

Serial operation occurs when S\_LOAD is LOW. The shift register is loaded by sampling the S\_DATA bits with the rising edge of S\_CLOCK. The contents of the shift register are loaded into the M, N and P dividers when S\_LOAD transitions from LOW-to-HIGH. The divide values are latched on the HIGH-to-LOW transition of S\_LOAD. If S\_LOAD is held HIGH, data at the S\_DATA input is passed directly to the dividers on each rising edge of S\_CLOCK. The serial mode can be used to program the M, N and P bits.

Figure 1. Serial Load Operation

**Table 1. Pin Descriptions**

Number	Name	Type		Description
1, 4, 8	V <sub>DD</sub>	Power		Core supply pins.
2, 3	Q, nQ	Output		Differential output pair. LVDS interface levels.
5	S_LOAD	Input	Pulldown	Controls transition of data from shift register into the dividers. LVCMOS/LVTTL interface levels.
6	S_DATA	Input	Pulldown	Shift register serial input. Data sampled on the rising edge of S_CLOCK. LVCMOS/LVTTL interface levels.
7	S_CLOCK	Input	Pulldown	Clocks in serial data present at S_DATA input into the shift register on the rising edge of S_CLOCK. LVCMOS/LVTTL interface levels.
9	CLK	Input	Pulldown	Non-inverting differential clock input.
10	nCLK	Input	Pullup/Pulldown	Inverting differential clock input. V <sub>DD</sub> /2 default when left floating.
11, 20	GND	Power		Negative supply pin.
12	CLK_SEL	Input	Pullup	Selects the reference clock. When LOW selects SE_CLK as the clock source. When HIGH selects CLK, nCLK as the clock source. LVCMOS/LVTTL interface levels.
13	SE_CLK	Input	Pulldown	Single-ended clock input. LVCMOS/LVTTL interface levels.
14	BYPASS	Input	Pulldown	Selects between the PLL and reference clock as the input to the dividers. When LOW, selects PLL. When HIGH, selects reference clock. LVCMOS/LVTTL interface levels.
15	FB_IN	Input	Pulldown	Non-inverting differential clock input.
16	nFB_IN	Input	Pullup/Pulldown	Inverting differential clock input. V <sub>DD</sub> /2 default when left floating.
17	V <sub>DDA</sub>	Power		Analog supply pin.
18, 19	QFB, nQFB	Output		Differential output pair. LVDS interface levels.

NOTE: *Pullup* and *Pulldown* refer to internal input resistors. See Table 2, *Pin Characteristics*, for typical values.

**Table 2. Pin Characteristics**

Symbol	Parameter	Test Conditions	Minimum	Typical	Maximum	Units
C <sub>IN</sub>	Input Capacitance			4		pF
R <sub>PULLUP</sub>	Input Pullup Resistor			51		kΩ
R <sub>PULLDOWN</sub>	Input Pulldown Resistor			51		kΩ

## Function Tables

Table 3A. Parallel and Serial Mode Function Table

Inputs			Conditions
S_LOAD	S_CLOCK	S_DATA	
L	X	X	Data is latched into input registers and remains loaded until next LOW transition or until a serial event occurs.
L	↑	Data	Shift register is loaded with data on S_DATA on each rising edge of S_CLOCK.
↑	L	Data	Contents of the shift register are passed to the M, N and P dividers.
↓	L	Data	M, N and P divider values are latched.
L	X	X	Serial input do not affect shift registers.
H	↑	Data	S_DATA passed directly to M, N and P dividers as it is clocked.

NOTE: L = LOW  
 H = HIGH  
 X = Don't care  
 ↑ = Rising edge transition  
 ↓ = Falling edge transition

## Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics* or *AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

Item	Rating
Supply Voltage, $V_{DD}$	4.6V
Inputs, $V_I$	-0.5V to $V_{DD} + 0.5V$
Outputs, $I_O$ (LVDS) Continuous Current Surge Current	10mA 15mA
Outputs, $I_O$ (LVDS) Continuous Current Surge Current	50mA 100mA
Package Thermal Impedance, $\theta_{JA}$	87.2°C/W (0 mps)
Storage Temperature, $T_{STG}$	-65°C to 150°C

## DC Electrical Characteristics

### Wiring the Differential Input to Accept Single-Ended Levels

Figure 2 shows how the differential input can be wired to accept single-ended levels. The reference voltage  $V_{REF} = V_{DD}/2$  is generated by the bias resistors R1, R2 and C1. This bias circuit should be located as close as possible to the input pin. The ratio of R1 and R2 might need to be adjusted to position the  $V_{REF}$  in the center of the input voltage swing. For example, if the input clock swing is only 2.5V and  $V_{DD} = 3.3V$ ,  $V_{REF}$  should be 1.25V and  $R2/R1 = 0.609$ .

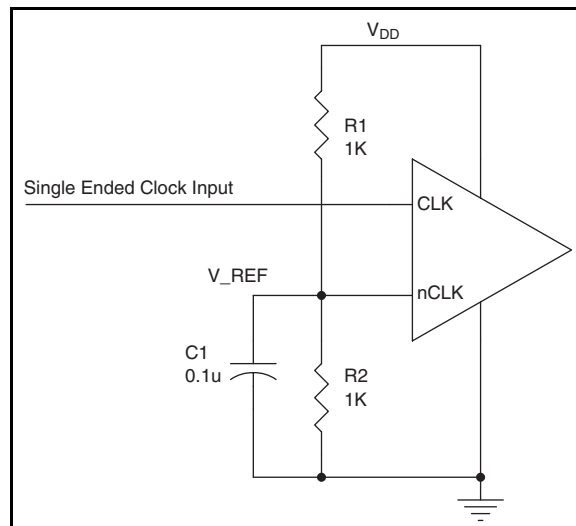

Figure 2. Single-Ended Signal Driving Differential Input

### Differential Clock Input Interface

The CLK /nCLK accepts LVDS, LVPECL, LVHSTL, SSTL, HCSL and other differential signals. Both  $V_{SWING}$  and  $V_{OH}$  must meet the  $V_{PP}$  and  $V_{CMR}$  input requirements. Figures 3A to 3F show interface examples for the HiPerClockS CLK/nCLK input driven by the most common driver types. The input interfaces suggested here are examples only. Please consult with the vendor of the driver

component to confirm the driver termination requirements. For example, in Figure 3A, the input termination applies for IDT HiPerClockS open emitter LVHSTL drivers. If you are using an LVHSTL driver from another vendor, use their termination recommendation.

## Power Supply Filtering Technique

As in any high speed analog circuitry, the power supply pins are vulnerable to random noise. The ICS874S336 provides separate power supplies to isolate any high switching noise from the outputs to the internal PLL.  $V_{DD}$  and  $V_{DDA}$  should be individually connected to the power supply plane through vias, and bypass capacitors should be used for each pin. To achieve optimum jitter performance, power supply isolation is required. *Figure 4* illustrates how a  $10\Omega$  resistor along with a  $10\mu\text{F}$  and a  $0.01\mu\text{F}$  bypass capacitor should be connected to each  $V_{DDA}$  pin.

Figure 4. Power Supply Filtering

## Recommendations for Unused Input and Output Pins

### Inputs:

#### CLK/nCLK Inputs

For applications not requiring the use of the differential input, both CLK and nCLK can be left floating. Though not required, but for additional protection, a  $1\text{k}\Omega$  resistor can be tied from CLK to ground.

#### SE\_CLK Input

For applications not requiring the use of a clock input, it can be left floating. Though not required, but for additional protection, a  $1\text{k}\Omega$  resistor can be tied from the SE\_CLK input to ground.

#### LVC MOS Control Pins

All control pins have internal pull-ups or pull-downs; additional resistance is not required but can be added for additional protection. A  $1\text{k}\Omega$  resistor can be used.

### Outputs:

#### LVDS Outputs

All unused LVDS output pairs can be either left floating or terminated with  $100\Omega$  across. If they are left floating, there should be no trace attached.

## 3.3V LVDS Driver Termination

A general LVDS interface is shown in *Figure 5*. In a  $100\Omega$  differential transmission line environment, LVDS drivers require a matched load termination of  $100\Omega$  across near the receiver input.

For a multiple LVDS outputs buffer, if only partial outputs are used, it is recommended to terminate the unused outputs.

Figure 5. Typical LVDS Driver Termination

### Schematic Example

Figure 6 shows an example of ICS874S336 application schematic. In this example, the device is operated at  $V_{DD} = 3.3V$ . The decoupling capacitors should be located as close as possible to

the power pin. Two examples of LVDS terminations are shown in this schematic. The input is driven either by a 3.3V LVPECL driver or a 3.3V LVCMOS . .

Figure 6. ICS874S336 Schematic Example

## Power Considerations

This section provides information on power dissipation and junction temperature for the ICS874S336. Equations and example calculations are also provided.

### 1. Power Dissipation.

The total power dissipation for the ICS74S336 is the sum of the core power plus the power dissipated in the load(s). The following is the power dissipation for  $V_{DD} = 3.3V + 5\% = 3.465V$ , which gives worst case results.

- Power (core)<sub>MAX</sub> =  $V_{DD\_MAX} * (I_{DD\_MAX} + I_{DDA\_MAX}) = 3.465V * (115mA + 15mA) = 450.45mW$

### 2. Junction Temperature.

Junction temperature,  $T_j$ , is the temperature at the junction of the bond wire and bond pad and directly affects the reliability of the device. The maximum recommended junction temperature for HiPerClockS devices is 125°C.

The equation for  $T_j$  is as follows:  $T_j = \theta_{JA} * Pd\_total + T_A$

$T_j$  = Junction Temperature

$\theta_{JA}$  = Junction-to-Ambient Thermal Resistance

$Pd\_total$  = Total Device Power Dissipation (example calculation is in section 1 above)

$T_A$  = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance  $\theta_{JA}$  must be used. Assuming no air flow and a multi-layer board, the appropriate value is 87.2°C/W per Table 7 below.

Therefore,  $T_j$  for an ambient temperature of 70°C with all outputs switching is:

$$70^\circ\text{C} + 0.450\text{W} * 87.2^\circ\text{C}/\text{W} = 109.2^\circ\text{C}. \text{ This is well below the limit of } 125^\circ\text{C}.$$

This calculation is only an example.  $T_j$  will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (single layer or multi-layer).

**Table 7. Thermal Resistance  $\theta_{JA}$  for 20 Lead TSSOP, Forced Convection**

Meters per Second	$\theta_{JA}$ by Velocity		
	0	1	2.5
Multi-Layer PCB, JEDEC Standard Test Boards	87.2°C/W	82.9°C/W	80.7°C/W
