## 2:1 PCIE GEN1/2/3 CLOCK MULTIPLEXER

IDT5V41068A

### Description

The IDT5V41068A is a 2:1 differential clock mux for PCI Express applications. It has very low additive jitter making it suitable for use in PCIe Gen2 and Gen3 systems. The IDT5V41068A selects between 1 of 2 differential HCSL inputs to drive a single differential HCSL output pair. The output can also be terminated to LVDS.

### Recommended Applications

- Clock muxing in PCIe Gen2 and Gen3 applications

### Output Features

- 1 – 0.7V current mode differential HCSL output pair

### Features/Benefits

- Low additive jitter; suitable for use in PCIe Gen2 and Gen3 systems
- 16-pin TSSOP package; small board footprint
- Outputs can be terminated to LVDS; can drive a wider variety of devices
- OE control pin; greater system power management
- Industrial temperature range available; supports demanding embedded applications

### Key Specifications

- Additive cycle-to-cycle jitter <5 ps
- Additive phase jitter (PCIe Gen3) <0.2ps
- Operating frequency up to 200MHz

## Pin Descriptions

PIN #	PIN NAME	PIN TYPE	DESCRIPTION
1	VDDIN	PWR	Power pin for the Inputs, nominal 3.3V
2	DIF_IN1	IN	0.7 V Differential TRUE input
3	DIF_IN1#	IN	0.7 V Differential Complementary Input
4	^PD#	IN	Asynchronous active low input pin used to power down the device. The internal clocks are disabled and the VCO and the crystal osc. (if any) are stopped.
5	DIF_IN2	IN	0.7 V Differential TRUE input
6	DIF_IN2#	IN	0.7 V Differential Complementary Input
7	^OE	IN	Active high input for enabling outputs. This pin has an internal pull up resistor. 0 = disable outputs, 1= enable outputs
8	GND	PWR	Ground pin.
9	IREF	OUT	This pin establishes the reference for the differential current-mode output pairs. It requires a fixed precision resistor to ground. 475ohm is the standard value for 100ohm differential impedance. Other impedances require different values. See data sheet.
10	VDD	PWR	Power supply, nominal 3.3V
11	VDD	PWR	Power supply, nominal 3.3V

15	DIF_0	OUT	0.7V differential true clock output
16	^SEL	IN	Selects between one of two inputs. This pin has internal pull up resistor.

## Application Information

### Decoupling Capacitors

As with any high-performance mixed-signal IC, the IDT5V41068A must be isolated from system power supply noise to perform optimally.

Decoupling capacitors of 0.01 $\mu$ F must be connected between each VDD and the PCB ground plane.

### PCB Layout Recommendations

For optimum device performance and lowest output phase noise, the following guidelines should be observed.

Each 0.01 $\mu$ F decoupling capacitor should be mounted on the component side of the board as close to the VDD pin as possible. No vias should be used between decoupling capacitor and VDD pin. The PCB trace to VDD pin should be kept as short as possible, as should the PCB trace to the ground via. Distance of the ferrite bead and bulk decoupling from the device is less critical.

2) An optimum layout is one with all components on the same side of the board, minimizing vias through other signal layers (the ferrite bead and bulk decoupling capacitor can be mounted on the back). Other signal traces should be routed away from the IDT5V41068A.

This includes signal traces just underneath the device, or on layers adjacent to the ground plane layer used by the device.

### External Components

A minimum number of external components are required for proper operation. Decoupling capacitors of 0.01  $\mu$ F should be connected between VDD and GND pairs (2,9 and 15,16) as close to the device as possible.

### Current Reference Source $R_r$ ( $I_{ref}$ )

If board target trace impedance ( $Z$ ) is 50 $\Omega$ , then  $R_r = 475\Omega$  (1%), providing IREF of 2.32 mA, output current ( $I_{OH}$ ) is equal to 6\*IREF.

### Load Resistors $R_L$

Since the clock outputs are open source outputs, 50 ohm external resistors to ground are to be connected at each clock output.

### Output Termination

The PCI-Express differential clock outputs of the IDT5V41068A are open source drivers and require an external series resistor and a resistor to ground. These resistor values and their allowable locations are shown in detail in the **Layout Guidelines** section.

The IDT5V41068A can also be terminated to LVDS compatible voltage levels. See the **Layout Guidelines** section.

## Output Structures

### General PCB Layout Recommendations

For optimum device performance and lowest output phase noise, the following guidelines should be observed.

1. Each  $0.01 \mu\text{F}$  decoupling capacitor should be mounted on the component side of the board as close to the VDD pin as possible.
2. No vias should be used between decoupling capacitor and VDD pin.
3. The PCB trace to VDD pin should be kept as short as possible, as should the PCB trace to the ground via. Distance of the ferrite bead and bulk decoupling from the device is less critical.
4. An optimum layout is one with all components on the same side of the board, minimizing vias through other signal layers (any ferrite beads and bulk decoupling capacitors can be mounted on the back). Other signal traces should be routed away from the IDT5V41068A. This includes signal traces just underneath the device, or on layers adjacent to the ground plane layer used by the device.

## Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the IDT5V41068A. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

<sup>1</sup> Guaranteed by design and characterization, not 100% tested in production. I<sub>REF</sub> = VDD/(3xR<sub>R</sub>). For R<sub>R</sub> = 475Ω (1%), I<sub>REF</sub> = 2.32mA.

I<sub>OH</sub> = 6 x I<sub>REF</sub> and V<sub>OH</sub> = 0.7V @ Z<sub>O</sub>=50Ω (100Ω differential impedance).

<sup>2</sup> Measured from differential waveform

<sup>3</sup> Slew rate is measured through the V<sub>swing</sub> voltage range centered around differential 0V. This results in a +/-150mV window around differential 0V.

<sup>4</sup> Matching applies to rising edge rate of Clock / falling edge rate of Clock#. It is measured in a +/-75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope uses for the edge rate calculations.

<sup>5</sup> V<sub>cross</sub> is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

<sup>6</sup> The total variation of all V<sub>cross</sub> measurements in any particular system. Note that this is a subset of V<sub>cross\_min/max</sub> (V<sub>cross</sub> absolute) allowed. The intent is to limit V<sub>cross</sub> induced modulation by setting V<sub>cross\_delta</sub> to be smaller than V<sub>cross</sub> absolute.
