6-OUTPUT LOW POWER DIFFERENTIAL SYNTHESIZER FOR PCIE GEN2

9FGL699

Description

The 9FGL699 is a 6-output low-power clock sythesizer for PCIe Gen2. It runs from a 25MHz XTAL, provides spread spectrum capability, and has an SMBus for software control of the device.

Recommended Application

6-Output Low Power Differential Synthesizer for PCIe Gen2

Output Features

- 6 - 100MHz Differential low power push pull (HCSL compatible) output pairs

Features/Benefits

- 32-pin QFN; Space-savings
- Push Pull outputs; Low power consumption, reduced component count
- PCIe Gen2; Supports latest systems
- Spread Spectrum Capability; reduced EMI when needed
- D2/D3 SMBus Write/Read SMBus address

Key Specifications

- Cycle-to-cycle jitter < 85ps
- Output-to-output skew < 100 ps
- Current consumption < 40mA
- PCIe Gen2 phase jitter < 3.0ps RMS

How to Write

- Controller (host) sends a start bit
- Controller (host) sends the write address
- IDT clock will **acknowledge**
- Controller (host) sends the beginning byte location = N
- IDT clock will **acknowledge**
- Controller (host) sends the byte count = X
- IDT clock will **acknowledge**
- Controller (host) starts sending Byte **N through Byte N+X-1**
- IDT clock will **acknowledg**e each byte **one at a time**
- Controller (host) sends a Stop bit

Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the 9FGL699. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

[1]Guaranteed by design and characterization, not 100% tested in production. C_L = 2pF with R_S = 33Ω for Zo = 50Ω (100Ω differential trace impedance).

[2] Measured from differential waveform

[3] Slew rate is measured through the Vswing voltage range centered around differential 0V. This results in a +/-150mV window around differential 0V.

[4] Matching applies to rising edge rate of Clock / falling edge rate of Clock#. It is measured in a +/-75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope uses for the edge rate calculations.

[5] Vcross is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

[6] The total variation of all Vcross measurements in any particular system. Note that this is a subset of V_cross_min/max (V_cross absolute) allowed. The intent is to limit Vcross induced modulation by setting V_cross_delta to be smaller than V_cross abs.
