General Description

The 83115 is a low skew, 1-to-16 LVCMOS/ LVTTL Fanout Buffer from IDT. The 83115 single-ended clock input accepts LVCMOS or LVTTL input levels. The 83115 operates at full 3.3V supply mode over the commercial temperature range. Guaranteed output and part-to-part skew characteristics make the 83115 ideal for those clock distribution applications demanding well defined performance and repeatability.

Features

- Sixteen LVCMOS / LVTTL outputs, 15Ω output impedance
- One LVCMOS / LVTTL clock input
- Maximum output frequency: 200MHz
- All inputs are 5V tolerant
- Output skew: 250ps (maximum)
- Part-to-part skew: 800ps (maximum)
- Additive phase jitter, RMS: 0.09ps (typical)
- Full 3.3V operating supply
- 0°C to 70°C ambient operating temperature
- Available in lead-free (RoHS 6) package

Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics or AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

t_{DIS}	Output Disable Time				20	ns

All parameters measured at f_{MAX} unless noted otherwise.
NOTE 1: Measured from V_{DD}/2 of the input to V_{DD}/2 of the output.
NOTE 2: Defined as skew between outputs at the same supply voltage and with equal load conditions. Measured at V_{DD}/2.
NOTE 3: Defined as skew between outputs on different devices operating at the same supply voltages and with equal load conditions. Using the same type of inputs on each device, the outputs are measured at V_{DD}/2.
NOTE 4: This parameter is defined in accordance with JEDEC Standard 65.

Additive Phase Jitter

The spectral purity in a band at a specific offset from the fundamental compared to the power of the fundamental is called the **dBc Phase Noise.** This value is normally expressed using a Phase noise plot and is most often the specified plot in many applications. Phase noise is defined as the ratio of the noise power present in a 1Hz band at a specified offset from the fundamental frequency to the power value of the fundamental. This ratio is expressed in decibels (dBm) or a ratio of the power in the 1Hz band

to the power in the fundamental. When the required offset is specified, the phase noise is called a **dBc** value, which simply means dBm at a specified offset from the fundamental. By investigating jitter in the frequency domain, we get a better understanding of its effects on the desired application over the entire time record of the signal. It is mathematically possible to calculate an expected bit error rate given a phase noise plot.

Additive Phase Jitter, RMS
@ 155.52MHz (12kHz to 20MHz) =
0.09ps (typical)

Offset Frequency (Hz)
As with most timing specifications, phase noise measurements has issues relating to the limitations of the equipment. Often the noise floor of the equipment is higher than the noise floor of the

device. This is illustrated above. The device meets the noise floor of what is shown, but can actually be lower. The phase noise is dependent on the input source and measurement equipment.

Recommendations for Unused Input and Output Pins

Inputs:

LVCMOS Control Pins

All control pins have internal pull-ups or pull-downs; additional resistance is not required but can be added for additional protection. A 1kΩ resistor can be used.

Outputs:

LVCMOS Outputs

All unused LVCMOS output can be left floating. There should be no trace attached.
