General Description

The ICS854S2021 is a 12:2 Differential-to-LVDS Clock Multiplexer which can operate up to 3GHz. The ICS854S2021 has twelve selectable differential clock inputs, any of which can be independently routed to either of the two LVDS outputs. The CLKx, nCLKx input pairs can accept LVPECL, LVDS, CML levels. The fully differential architecture and low propagation delay make it ideal for use in clock distribution circuits.

Features

- Two differential 3.3V LVDS clock outputs
- Twelve selectable differential clock inputs
- CLKx, nCLKx pairs can accept the following differential input levels: LVPECL, LVDS, CML
- Maximum output frequency: 3GHz
- Propagation delay: 1.1ns (maximum)
- Input skew: 100ps (maximum)
- Output skew: 50ps (maximum)
- Part-to-part skew: 250ps (maximum)
- Additive phase jitter, RMS (12kHz – 20MHz): 0.16ps (typical)
- Full 3.3V operating supply mode
- -40°C to 85°C ambient operating temperature

Pin Description and Pin Characteristic Tables

Table 1. Pin Descriptions

Number	Name	Type		Description
1	CLK2	Input	Pulldown	Non-inverting differential clock input.
2	nCLK2	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
3, 4, 9, 10	SELA_0, SELA_1, SELA_2, SELA_3	Input	Pulldown	Clock select pins for Bank A output pair. See Control Input Function Table. LVCMOS/LVTTL interface levels. See Table 3B.
5, 18, 32, 43	V_{DD}	Power		Power supply pins.
6, 7	QA, nQA	Output		Clock outputs. LVDS interface levels.
8, 15, 22, 29, 39, 46	GND	Power		Power supply ground.
11	CLK3	Input	Pulldown	Non-inverting differential clock input.
12	nCLK3	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
13	nCLK4	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
14	CLK4	Input	Pulldown	Non-inverting differential clock input.
16	nCLK5	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
17	CLK5	Input	Pulldown	Non-inverting differential clock input.
18, 43	V_{DD}	Power		Positive supply pins.
19	OEA	Input	Pullup	Output enable pin. Controls enabling and disabling of QA, nQA output pair. LVCMOS/LVTTL interface levels.
20	CLK6	Input	Pulldown	Non-inverting differential clock input.
21	nCLK6	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
23	CLK7	Input	Pulldown	Non-inverting differential clock input.
24	nCLK7	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
25	nCLK8	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
26	CLK8	Input	Pulldown	Non-inverting differential clock input.
27, 28, 33, 34	SELB_3, SELB_2, SELB_1, SELB_0	Input	Pulldown	Clock select pins for Bank B output pair. See Control Input Function Table. LVCMOS/LVTTL interface levels. See Table 3C.
30, 31	nQB, QB	Output		Clock outputs. LVDS interface levels.
35	nCLK9	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
36	CLK9	Input	Pulldown	Non-inverting differential clock input.
37	nCLK10	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
38	CLK10	Input	Pulldown	Non-inverting differential clock input.
40	nCLK11	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
41	CLK11	Input	Pulldown	Non-inverting differential clock input.
42	OEB	Input	Pullup	Output enable pin. Controls enabling and disabling of QB, nQB output pair. LVCMOS/LVTTL interface levels.
44	CLK0	Input	Pulldown	Non-inverting differential clock input.

Number	Name	Type		Description
45	nCLK0	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.
47	CLK1	Input	Pulldown	Non-inverting differential clock input.
48	nCLK1	Input	Pullup/Pulldown	Inverting differential clock input. $V_{DD}/2$ default when left floating.

NOTE: *Pullup and Pulldown* refer to internal input resistors. See Table 2, Pin Characteristics, for typical values.

Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics* or *AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

Item	Rating
Supply Voltage, V_{DD}	4.6V
Inputs, V_I	-0.5V to $V_{DD} + 0.5V$
Outputs, I_O (LVDS) Continuous Current Surge Current	10mA 15mA
Package Thermal Impedance, θ_{JA}	70.2°C/W (0 mps)
Storage Temperature, T_{STG}	-65°C to 150°C

DC Characteristic Tables

t_R / t_F	Output Rise/Fall Time	20% to 80%	50	110	250	ps
odc	Output Duty Cycle; NOTE 6		40	50	60	%
$MUX_{ISOLATION}$	MUX Isolation	$f_{OUT} < 1.2GHz$		75		dB

NOTE: Electrical parameters are guaranteed over the specified ambient operating temperature range. Note that phase noise may increase slightly with higher operating temperature. However, they will remain in spec as long as the maximum transistor junction temperature is not violated. The device will meet specifications after thermal equilibrium has been reached under these conditions.

NOTE 1: Measured from the differential input cross point to the differential output cross point.

NOTE 2: Defined as skew between outputs at the same supply voltage and with equal load conditions. Measured at the differential output cross point.

NOTE 3: This parameter is defined in accordance with JEDEC Standard 65.

NOTE 4: Defined as skew between outputs on different devices operating at the same supply voltage, same frequency, same temperature and with equal load conditions. Using the same type of input on each device, measured at the differential output cross point.

NOTE 5: Driving only one input clock.

NOTE 6: The output duty cycle will depend on the input duty cycle.

Additive Phase Jitter

The spectral purity in a band at a specific offset from the fundamental compared to the power of the fundamental is called the *dBc Phase Noise*. This value is normally expressed using a Phase noise plot and is most often the specified plot in many applications. Phase noise is defined as the ratio of the noise power present in a 1Hz band at a specified offset from the fundamental frequency to the power value of the fundamental. This ratio is expressed in decibels (dBm) or a ratio

of the power in the 1Hz band to the power in the fundamental. When the required offset is specified, the phase noise is called a *dBc* value, which simply means dBm at a specified offset from the fundamental. By investigating jitter in the frequency domain, we get a better understanding of its effects on the desired application over the entire time record of the signal. It is mathematically possible to calculate an expected bit error rate given a phase noise plot.

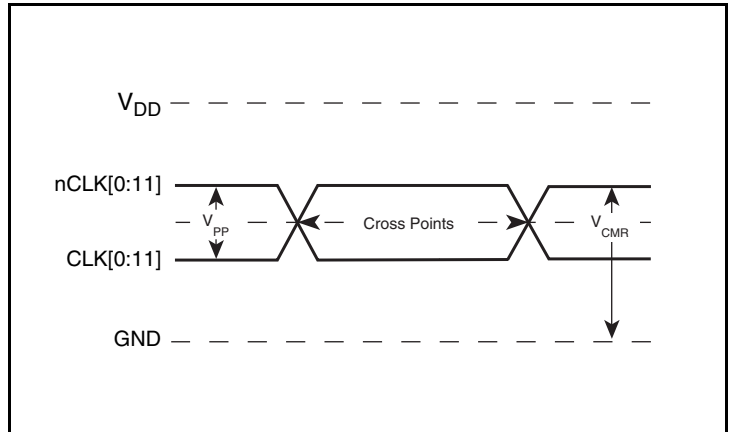

As with most timing specifications, phase noise measurements have issues. The primary issue relates to the limitations of the equipment. Often the noise floor of the equipment is higher than the noise floor of the device. This is illustrated above. The device meets the noise floor of what is shown, but can actually be lower. The phase noise is dependent on the input source and measurement equipment.

Used the Rhode & Schwartz SMA100 as the input source.

Recommendations for Unused Input and Output Pins

Inputs:

CLK/nCLK Inputs

For applications requiring only one differential input, the unused CLK and nCLK input can be left floating. Though not required, but for additional protection, a 1k Ω resistor can be tied from CLK pin to ground.

LVC MOS Control Pins

All control pins have internal pullups or pulldowns; additional resistance is not required but can be added for additional protection. A 1k Ω resistor can be used.

Outputs:

LVDS Outputs

All unused LVDS output pairs can be either left floating or terminated with 100 Ω across. If they are left floating, there should be no trace attached

Wiring the Differential Input to Accept Single-Ended Levels

Figure 1 shows how a differential input can be wired to accept single ended levels. The reference voltage $V_1 = V_{DD}/2$ is generated by the bias resistors R1 and R2. The bypass capacitor (C1) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of R1 and R2 might need to be adjusted to position the V_1 in the center of the input voltage swing. For example, if the input clock swing is 2.5V and $V_{DD} = 3.3V$, R1 and R2 value should be adjusted to set V_1 at 1.25V. The values below are for when both the single ended swing and V_{DD} are at the same voltage. This configuration requires that the sum of the output impedance of the driver (R_o) and the series resistance (R_s) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in one of two ways. First, R3 and R4 in parallel should equal the transmission line

impedance. For most 50 Ω applications, R3 and R4 can be 100 Ω . The values of the resistors can be increased to reduce the loading for slower and weaker LVC MOS driver. When using single-ended signaling, the noise rejection benefits of differential signaling are reduced. Even though the differential input can handle full rail LVC MOS signaling, it is recommended that the amplitude be reduced. The datasheet specifies a lower differential amplitude, however this only applies to differential signals. For single-ended applications, the swing can be larger, however V_{IL} cannot be less than -0.3V and V_{IH} cannot be more than $V_{DD} + 0.3V$. Though some of the recommended components might not be used, the pads should be placed in the layout. They can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a differential signal.

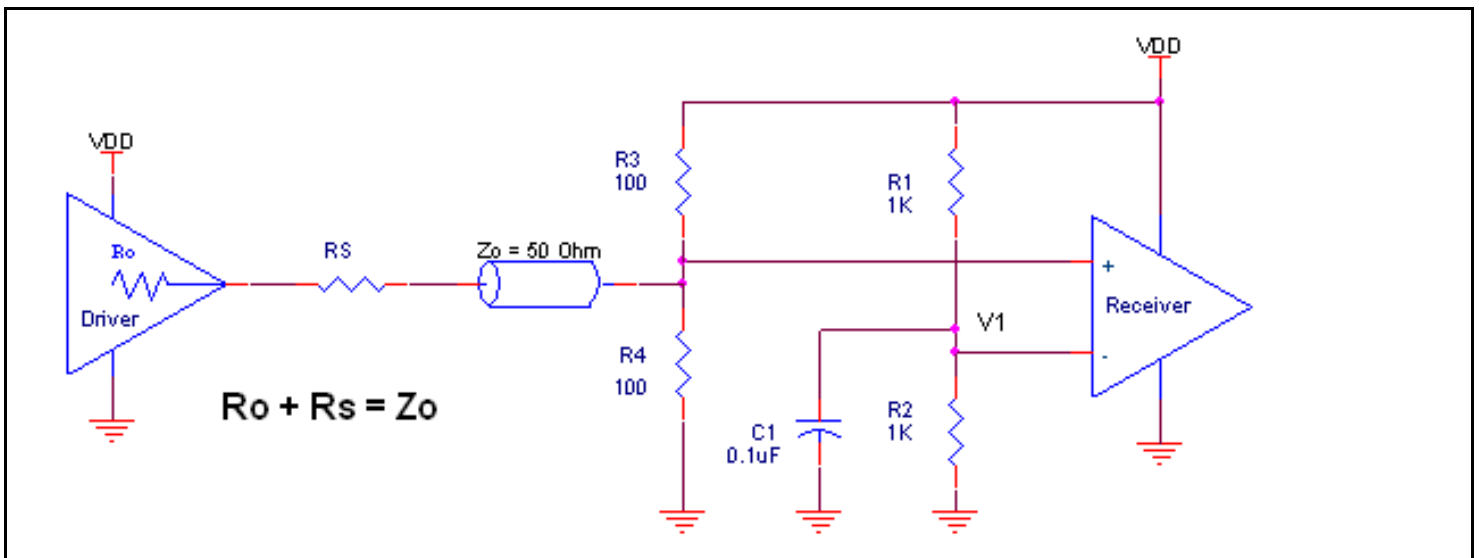

Figure 1. Recommended Schematic for Wiring a Differential Input to Accept Single-ended Levels

3.3V Differential Clock Input Interface

The CLK /nCLK accepts LVDS, LVPECL, CML and other differential signals. Both V_{SWING} and V_{OH} must meet the V_{PP} and V_{CMR} input requirements. *Figures 2A to 2E* show interface examples for the CLK/nCLK input driven by the most common driver types. The input

interfaces suggested here are examples only. If the driver is from another vendor, use their termination recommendation. Please consult with the vendor of the driver component to confirm the driver termination requirements.

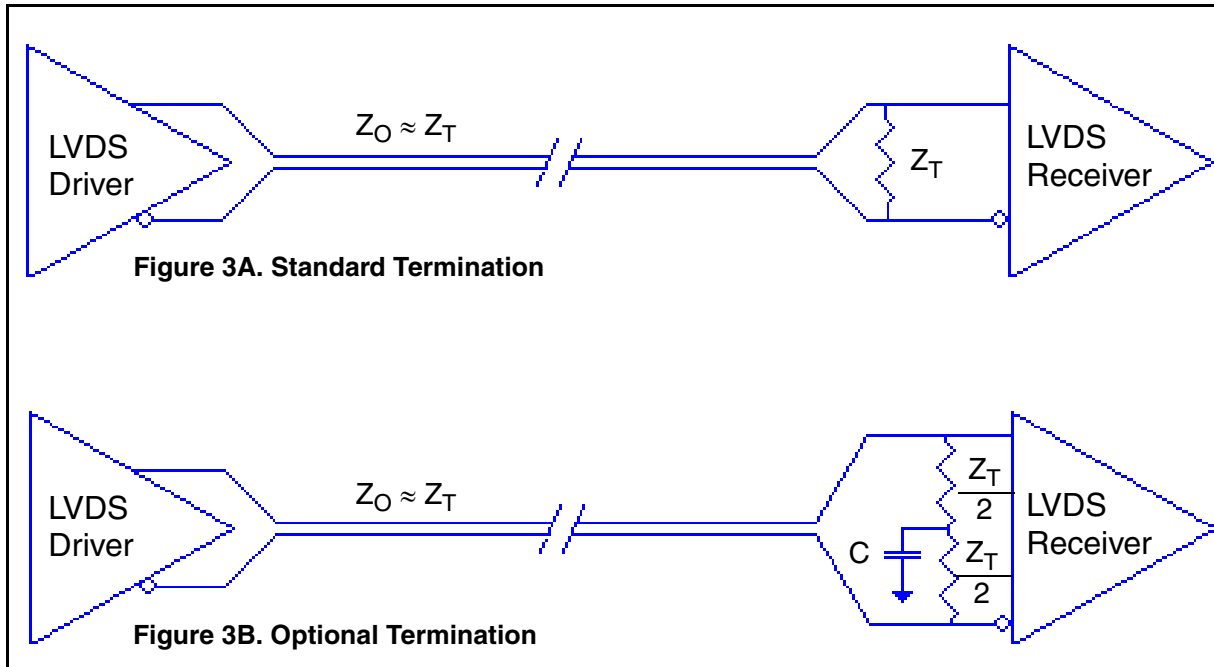

Figure 2E. CLK/nCLK Input Driven by a 3.3V LVDS Driver

LVDS Driver Termination

For a general LVDS interface, the recommended value for the termination impedance (Z_T) is between 90Ω and 132Ω . The actual value should be selected to match the differential impedance (Z_0) of your transmission line. A typical point-to-point LVDS design uses a 100Ω parallel resistor at the receiver and a 100Ω differential transmission-line environment. In order to avoid any transmission-line reflection issues, the components should be surface mounted and must be placed as close to the receiver as possible. IDT offers a full line of LVDS compliant devices with two types of output structures: current source and voltage source. The

standard termination schematic as shown in *Figure 3A* can be used with either type of output structure. *Figure 3B*, which can also be used with both output types, is an optional termination with center tap capacitance to help filter common mode noise. The capacitor value should be approximately 50pF . If using a non-standard termination, it is recommended to contact IDT and confirm if the output structure is current source or voltage source type. In addition, since these outputs are LVDS compatible, the input receiver's amplitude and common-mode input range should be verified for compatibility with the output.

LVDS Termination

LVDS Power Considerations

This section provides information on power dissipation and junction temperature for the ICS854S202I. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the ICS854S202I is the sum of the core power plus the output power dissipated due to the load. The following is the power dissipation for $V_{DD} = 3.3V + 5\% = 3.465V$, which gives worst case results.

- $Power_{MAX} = V_{DD_MAX} * I_{DD_MAX} = 3.465V * 138mA = 478.17mW$

2. Junction Temperature.

Junction temperature, T_j , is the temperature at the junction of the bond wire and bond pad directly affects the reliability of the device. The maximum recommended junction temperature is 125°C. Limiting the internal transistor junction temperature, T_j , to 125°C ensures that the bond wire and bond pad temperature remains below 125°C.

The equation for T_j is as follows: $T_j = \theta_{JA} * Pd_{total} + T_A$

T_j = Junction Temperature

θ_{JA} = Junction-to-Ambient Thermal Resistance

Pd_{total} = Total Device Power Dissipation (example calculation is in section 1 above)

T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming no air flow and a multi-layer board, the appropriate value is 70.2°C/W per Table 6 below.

Therefore, T_j for an ambient temperature of 85°C with all outputs switching is:

$$85^\circ\text{C} + 0.478\text{W} * 70.2^\circ\text{C/W} = 118.6^\circ\text{C}. \text{ This is below the limit of } 125^\circ\text{C}.$$

This calculation is only an example. T_j will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).

Table 6. Thermal Resistance θ_{JA} for 48 Lead LQFP, Forced Convection

Meters per Second	θ_{JA} by Velocity		
	0	1	2.5
