## LOW JITTER AND SKEW 10 TO 220 MHz ZERO DELAY BUFFER (ZDB)

### Features

- 10 to 220 MHz operating frequency range
- Low output clock jitter:
  - 50 ps-typ cycle-to-cycle jitter
  - 20 ps-typ period jitter
- Low output-to-output skew: 30 ps-typ
- Low product-to-product skew: 60 ps-typ
- Wide 2.5 V to 3.3 V power supply range
- Low power dissipation:
  - 16 mA-max at 66 MHz and VDD = 3.3 V
  - 14 mA-max at 66 MHz and VDD = 2.5 V
- One input drives five outputs organized as 4+1
- SpreadThru™ PLL that allows use of SSCG
- Standard and High-Drive options
- Available in 8 pin SOIC and TSSOP packages
- Available in Commercial and Industrial grades

### Applications

- Printers and MFPs
- Digital Copiers
- PCs and Work Stations
- Routers, Switchers and Servers
- Digital Embedded Systems

### Benefits

- Up to five distribution of input clock
- Standard and High-Drive levels to control impedance level, frequency range and EMI
- Low power dissipation, jitter and skew
- Low cost

### Description

The SL23EP05 is a low skew, low jitter, and low power Zero Delay Buffer (ZDB) designed to produce up to five clock outputs from one reference input clock for high speed clock distribution applications. The product has an on-chip PLL which locks to the input clock at CLKIN and receives its feedback internally from the CLKOUT pin.

The SL23EP05 is available with two drive strength versions called -1 and -1H. The -1 is the standard-drive version and -1H is the high-drive version.

The SL23EP05 high-drive version operates up to 220 MHz and 180 MHz at 3.3 V and 2.5 V power supplies, respectively. The standard drive version -1 operates up to 200 MHz and 167 MHz at 3.3 V and 2.5 V, respectively.

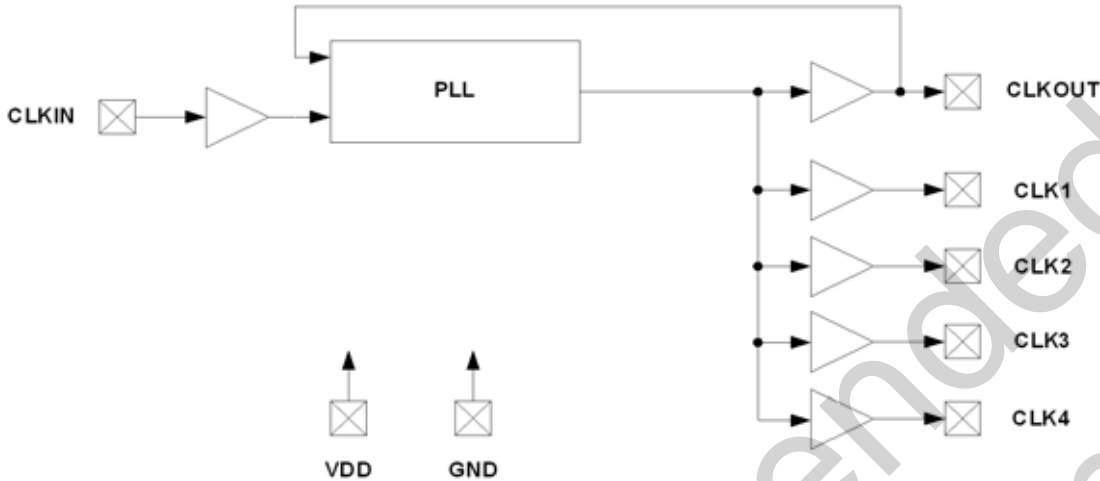

The SL23EP05 enter into Power Down (PD) mode if the input at CLKIN is less than 2.0 MHz or there is no rising edge. In this state all five outputs are tri-stated and the PLL is turned off leading to less than 10  $\mu$ A of power supply current draw.

## 2. General Description

The SL23EP05 is a low skew, low jitter Zero Delay Buffer with very low operating current.

The product includes an on-chip high performance PLL that locks into the input reference clock and produces five output clock drivers tracking the input reference clock for systems requiring clock distribution.

## 3. Input and Output Frequency Range

The input and output frequency range is the same. However, it depends on  $V_{DD}$  and drive levels as given in the below Table 8.

**Table 8. Input/Output Frequency Range**

$V_{DD}$ (V)	Drive	Min (MHz)	Max (MHz)
3.3	HIGH	10	220
3.3	STD	10	200
2.5	HIGH	10	180
2.5	STD	10	167

If the input clock frequency is DC (0 to  $V_{DD}$ ), this is detected by an input frequency detection circuitry and all five clock outputs are forced to Hi-Z. The PLL is shutdown to save power. In this shutdown state, the product draws less than 10  $\mu$ A supply current.

## 4. SpreadThru™ Feature

If a Spread Spectrum Clock (SSC) were to be used as an input clock, the SL23EP05 is designed to pass the modulated Spread Spectrum Clock (SSC) signal from its reference input to the output clocks. The same spread characteristics at the input are passed through the PLL and drivers without any degradation in spread percent (%), spread profile and modulation frequency.

## 5. High and Low-Drive Product Options

The SL23EP05 is offered with High-Drive “-1H” and Standard-Drive “-1” options. These drive options enable the users to control load levels, frequency range and EMI control. Refer to the AC electrical tables for the details.

## 6. Skew and Zero Delay

All outputs should drive the similar load to achieve output-to-output skew and input-to-output specifications given in the AC electrical tables. However, Zero delay between input and outputs can be adjusted by changing the loading of CLKOUT relative to the banks A and B clocks since CLKOUT is the feedback to the PLL.

## 7. Power Supply Range ( $V_{DD}$ )

The SL23EP05 is designed to operate in a wide power supply range from 2.250 V (Min) to 3.360 V (Max). This power supply range complies with 3.3 V $\pm$ 10% and 2.5 V $\pm$ 10% standard power supply requirements used in most systems. An internal on-chip voltage regulator is used to supply PLL constant power supply of 1.8 V, leading to a consistent and stable PLL electrical performance in terms of skew, and jitter and power dissipation.

## 8. External Components and Design Considerations

Figure 1. Typical Application Schematic

### 8.1. Comments and Recommendations

**Decoupling Capacitor:** A minimum decoupling capacitor of 0.1  $\mu\text{F}$  must be used between VDD and VSS on the pins 6 and 4. Additional capacitors may be necessary depending on the application. Place the capacitor on the component side of the PCB as close to the VDD pin as possible. The PCB trace to the VDD pin and to the GND via should be kept as short as possible. Do not use vias between the decoupling capacitor and the VDD pin.

**Series Termination Resistor:** A series termination resistor is recommended if the distance between the output (SSCLK) and the load is over 1.5 inches. The nominal impedance of the SSCLK output is about 30  $\Omega$ . Use 20  $\Omega$  resistor in series with the output to terminate 50  $\Omega$  trace impedance and place 20  $\Omega$  resistor as close to the clock outputs as possible.

**Zero Delay and Skew Control:** All outputs and CLKIN pins should be loaded with the same load to achieve “Zero Delay” between the CLKIN and the outputs. The CLKOUT pin is connected to CLKIN internally on-chip for internal feedback to PLL, and sees an additional 2 pF load with respect to the clock pins. For applications requiring zero input/output delay, the load at the all output pins including the CLKOUT pin must be the same. If any delay adjustment is required, the capacitance at the CLKOUT pin could be increased or decreased to increase or decrease the delay between clocks and CLKIN.

For minimum pin-to-pin skew, the external load at the clocks must be the same.
