## +3V, 8-Bit ADC with 1µA Power-Down

MAX152

### General Description

The MAX152 high-speed, microprocessor (µP)-compatible, 8-bit analog-to-digital converter (ADC) uses a half-flash technique to achieve a 1.8µs conversion time, and digitizes at a rate of 400k samples per second (ksps). It operates with single +3V or dual ±3V supplies and accepts either unipolar or bipolar inputs. A POWERDOWN pin reduces current consumption to a typical value of 1µA. The part returns from power-down and acquires an input signal in less than 900ns, providing large reductions in supply current in applications with burst-mode input signals.

The MAX152 is DC and dynamically tested. Its µP interface appears as a memory location or input/output port that requires no external interface logic. The data outputs use latched, three-state buffered circuitry for direct connection to a µP data bus or system input port. The ADC's input/reference arrangement enables ratiometric operation. A fully-assembled evaluation kit provides a proven PC board layout to speed prototyping and design.

### Applications

- Cellular Telephones
- Portable Radios
- Battery-Powered Systems
- Burst-Mode Data Acquisition
- Digital Signal Processing
- Telecommunications
- High-Speed Servo Loops

### Functional Diagram

### Features

- ◆ **Single +3.0V to +3.6V Supply**
- ◆ **1.8µs Conversion Time**
- ◆ **Power-Up in 900ns**
- ◆ **Internal Track/Hold**
- ◆ **400ksps Throughput**
- ◆ **Low Power: 1.5mA (Operating Mode)  
1µA (Power-Down Mode)**
- ◆ **300kHz Full-Power Bandwidth**
- ◆ **20-Pin DIP, SO and SSOP Packages**
- ◆ **No External Clock Required**
- ◆ **Unipolar/Bipolar Inputs**
- ◆ **Ratiometric Reference Inputs**
- ◆ **2.7V Version Available – Contact Factory**

### Ordering Information

### Pin Description

PIN	NAME	FUNCTION
1	V <sub>IN</sub>	Analog Input. Range is VREF- ≤ V <sub>IN</sub> ≤ VREF+.
2	D0	Three-State Data Output (LSB)
3-5	D1-D3	Three-State Data Outputs
6	WR/RDY	Write Control Input/Ready Status Output*
7	MODE	Mode Selection Input is internally pulled low with a 15 $\mu$ A current source. MODE = 0 activates read mode. MODE = 1 activates write-read mode*
8	RD	Read Input must be low to access data.*
9	INT	Interrupt Output goes low to indicate end of conversion.*
10	GND	Ground
11	VREF-	Lower limit of reference span. Sets the zero-code voltage. Range is V <sub>SS</sub> ≤ VREF- < VREF+.
12	VREF+	Upper limit to reference span. Sets the full-scale input voltage. Range is VREF- < VREF+ ≤ V <sub>DD</sub> .
13	CS	Chip-Select Input must be low for the device recognize WR or RD inputs.
14-16	D4-D6	Three-State Data Outputs
17	D7	Three-State Data Output (MSB)
18	PWRDN	Powerdown Input reduces supply current when low.
19	V <sub>SS</sub>	Negative Supply. Unipolar: V <sub>SS</sub> = 0V, Bipolar: V <sub>SS</sub> = -3V.
20	V <sub>DD</sub>	Positive Supply, +3V.

\*See Digital Interface Section.

### Detailed Description

#### Converter Operation

The MAX152 uses a half-flash conversion technique (see *Functional Diagram*) in which two 4-bit flash ADC sections achieve an 8-bit result. Using 15 comparators, the flash ADC compares the unknown input voltage to the reference ladder and provides the upper 4 data bits.

An internal digital-to-analog converter (DAC) uses the 4 most significant bits (MSBs) to generate the analog result from the first flash conversion and a residue voltage that is the difference between the unknown input and the DAC voltage. The residue is then compared again with the flash comparators to obtain the lower 4 data bits (LSBs).

The MAX152 is characterized for operation between +3.0V and +3.6V. Conversion times decrease as the supply voltage increases. The supply current decreases rapidly with decreasing supply voltage. (See *Typical Operating Characteristics*.)

#### Power-Down Mode

In burst-mode or low sample-rate applications, the MAX152 can be shut down between conversions, reducing supply current to microamp levels (see *Typical Operating Characteristics*). A logic low on the PWRDN pin shuts the device down, reducing supply current to typically 1 $\mu$ A when powered from a single 3V supply. A logic high on PWRDN wakes up the MAX152. A new conversion can be started within 900ns of the PWRDN pin being driven high (this includes both the power-up delay and the track/hold acquisition time). If power-down mode is not required, connect PWRDN to V<sub>DD</sub>.

## +3V, 8-Bit ADC with 1 $\mu$ A Power-Down

Once the MAX152 is in power-down mode, lowest supply current is drawn with MODE low (RD mode) due to an internal pull-down resistor at this pin. In addition, for minimum current consumption, other digital inputs should remain high in power-down. Refer to the *Reference* section for information on reducing reference current during power-down.

### Digital Interface

The MAX152 has two basic interface modes set by the status of the MODE input pin. When MODE is low, the converter is in the RD mode; when MODE is high, the converter is set up for the WR-RD mode.

#### Read Mode (MODE = 0)

In RD mode, conversion control and data access are controlled by the  $\overline{\text{RD}}$  input (Figure 3). The comparator inputs track the analog input voltage for the duration of  $t_p$ . A conversion is initiated by driving  $\overline{\text{RD}}$  low. With  $\mu$ Ps that can be forced into a wait state, hold  $\overline{\text{RD}}$  low until output data appears. The  $\mu$ P starts the conversion, waits, and then reads data with a single read instruction.

$\overline{\text{WR}}/\text{RDY}$  is configured as a status output (RDY) in RD mode, where it can drive the ready or wait input of a  $\mu$ P. RDY is an open-collector output (with no internal pull-up) that goes low after the falling edge of  $\overline{\text{CS}}$  and goes high at the end of the conversion. If not used, the  $\overline{\text{WR}}/\text{RDY}$  pin can be left unconnected. The  $\overline{\text{INT}}$  output goes low at the end of the conversion and returns high on the rising edge of  $\overline{\text{CS}}$  or  $\overline{\text{RD}}$ .

Figure 3. RD Mode Timing (MODE = 0)

#### Write-Read Mode (MODE = 1)

Figures 4 and 5 show the operating sequence for the write-read (WR-RD) mode. The comparator inputs track the analog input voltage for the duration of  $t_p$ . The conversion is initiated by a falling edge of  $\overline{\text{WR}}$ . When  $\overline{\text{WR}}$  returns high, the 4 MSBs' flash result is latched into the output buffers and the 4 LSBs' conversion begins.  $\overline{\text{INT}}$  goes low, indicating conversion end, and the lower 4 data bits are latched into the output buffers. The data is then accessible after  $\overline{\text{RD}}$  goes low (see *Timing Characteristics*).

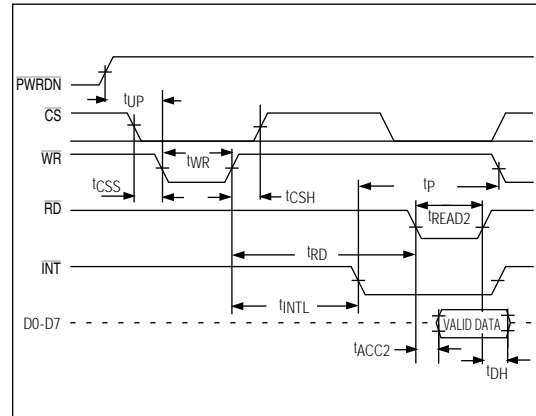

Figure 4. WR-RD Mode Timing ( $t_{RD} > t_{INTL}$ ) (MODE = 1)

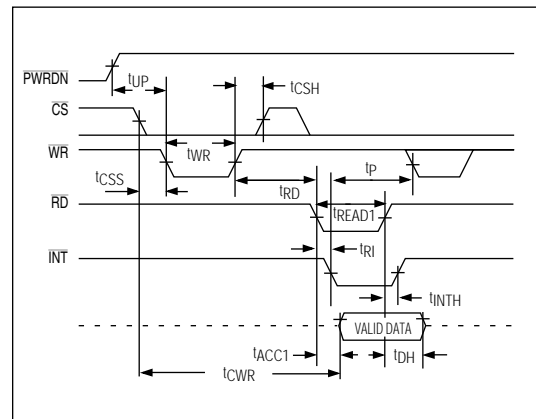

Figure 5. WR-RD Mode Timing ( $t_{RD} < t_{INTL}$ ), Fastest Operating Mode (MODE = 1)

## +3V, 8-Bit ADC with 1µA Power-Down

Figure 6. Stand-Alone Mode Timing ( $\overline{CS} = \overline{RD} = 0$ ) (MODE = 1)

A minimum acquisition time ( $t_p$ ) is required from  $\overline{INT}$  going low to the start of another conversion ( $\overline{WR}$  going low).

Options for reading data from the converter include the following:

### Using Internal Delay

The  $\mu P$  waits for the  $\overline{INT}$  output to go low before reading the data (Figure 4).  $\overline{INT}$  goes low after the rising edge of  $\overline{WR}$ , indicating that the conversion is complete and the result is available in the output latch. With  $\overline{CS}$  low, data outputs D0-D7 can be accessed by pulling  $\overline{RD}$  low.  $\overline{INT}$  is then reset by the rising edge of  $\overline{CS}$  or  $\overline{RD}$ .

### Fastest Conversion: Reading Before Delay

An external method of controlling the conversion time is shown in Figure 5. The internally generated delay  $t_{INTL}$  varies slightly with temperature and supply voltage, and can be overridden with  $\overline{RD}$  to achieve the fastest conversion time.  $\overline{RD}$  is brought low after the rising edge of  $\overline{WR}$ , but before  $\overline{INT}$  goes low. This completes the conversion and enables the output buffers (D0-D7) that contain the conversion result.  $\overline{INT}$  also goes low after the falling edge of  $\overline{RD}$  and is reset on the rising edge of  $\overline{RD}$  or  $\overline{CS}$ . The total conversion time is therefore:  $t_{CWR} = t_{WR} (600ns) + t_{RD} (800ns) + t_{ACC1} (400ns) = 1800ns$ .

### Stand-Alone Operation

Besides the two standard WR-RD mode options, stand-alone operation can be achieved by connecting  $\overline{CS}$  and  $\overline{RD}$  low (Figure 6). A conversion is initiated by pulling  $\overline{WR}$  low. Output data can be read by either edge of the next  $\overline{WR}$  pulse.

## +3V, 8-Bit ADC with 1 $\mu$ A Power-Down

### Analog Considerations

#### Reference

Figures 7a-7c show some reference connections. VREF+ and VREF- inputs set the full-scale and zero-input voltages of the ADC. The voltage at VREF- defines the input that produces an output code of all zeros, and the voltage at VREF+ defines the input that produces an output code of all ones.

The internal resistance from VREF+ to VREF- may be as low as 1k $\Omega$ , and current will flow through it even when the MAX152 is shut down. Figure 7d shows how an N-channel MOSFET may be connected to VREF- to break this path during power-down. The FET should have an on resistance < 2 $\Omega$  with a 3V gate drive.

Although VREF+ is frequently connected to VDD, this circuit uses a low current, low-dropout, 2.5V voltage reference – the MAX872. Since the MAX872 cannot continuously furnish enough current for the reference resistance, this circuit is intended for applications where the MAX152 is normally in standby and is turned on in order to make measurements at intervals greater than 20 $\mu$ s. The capacitor C1 connected to VREF+ is slowly charged by the MAX872 during the standby period and furnishes the reference current during the short measurement period.

The 2.2 $\mu$ F value of C1 is chosen so that its voltage drops by less than 1/2LSB during the conversion process. Larger capacitors reduce the error still further. Use ceramic or tantalum capacitors for C1.

When VREF- is switched, as in Figure 7d, a new conversion can be initiated after waiting a time equal to the power-up delay ( $t_{UP}$ ) plus the turn-on time of the N-channel FET.

#### Bypassing

A 4.7 $\mu$ F electrolytic in parallel with a 0.1 $\mu$ F ceramic capacitor should be used to bypass VDD to GND. These capacitors should have minimal lead length.

The reference inputs should be bypassed with 0.1 $\mu$ F capacitors, as shown in Figures 7a-7c.

#### Input Current

Figure 8 shows the equivalent circuit of the converter input. When the conversion starts and  $\overline{WR}$  is low,  $V_{IN}$  is connected to sixteen 0.6pF capacitors. During this acquisition phase, the input capacitors charge to the input voltage through the resistance of the internal analog switches. In addition, about 12pF of stray capacitance must be charged. The input can be modeled as an equivalent RC network (Figure 9). As source impedance increases, the capacitors take longer to charge.

The typical 22pF input capacitance allows source resistance as high as 2.2k $\Omega$  without setup problems. For larger resistances, the acquisition time ( $t_p$ ) must be increased.

Figure 8. Equivalent Input Circuit

Figure 9. RC Network Equivalent Input Model

## +3V, 8-Bit ADC with 1 $\mu$ A Power-Down

### Conversion Rate

The maximum sampling rate ( $f_{\max}$ ) for the MAX152 is achieved in the WR-RD mode ( $t_{RD} < t_{INTL}$ ) and is calculated as follows:

$$f_{\max} = \frac{1}{t_{WR} + t_{RD} + t_{RI} + t_P}$$

e.g. at  $T_A = +25^\circ\text{C}$ ,  $V_{DD} = +3.0\text{V}$ :

$$f_{\max} = \frac{1}{600\text{ns} + 800\text{ns} + 300\text{ns} + 450\text{ns}}$$

$$f_{\max} = 465\text{kHz}$$

where  $t_{WR}$  = Write pulse width

$t_{RD}$  = Delay between WR and RD pulses

$t_{RI}$  =  $\overline{\text{RD}}$  to  $\overline{\text{INT}}$  delay

$t_P$  = Delay time between conversions.

### Signal-to-Noise Ratio and Effective Number of Bits

Signal-to-noise plus distortion ratio (SINAD) is the ratio of the fundamental input frequency's RMS amplitude to the RMS amplitude of all other ADC output signals. The output band is limited to frequencies above DC and below one-half the ADC sample rate.

The theoretical minimum A/D noise is caused by quantization error, and results directly from the ADC's resolution:  $\text{SNR} = (6.02N + 1.76)\text{dB}$ , where N is the number of bits of resolution. Therefore, a perfect 8-bit ADC can do no better than 50dB.

The FFT plot (*Typical Operation Characteristics*) shows the result of sampling a pure 30.27kHz sinusoid at a 400kHz rate. This FFT plot of the output shows the output level in various spectral bands.

The effective resolution, or "effective number of bits," the ADC provides can be measured by transposing the equation that converts resolution to SNR:  $N = (\text{SINAD} - 1.76)/6.02$  (see *Typical Operating Characteristics*).

### Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the RMS sum of all harmonics of the input signal (in the frequency band above DC and below one-half the sample rate) to the fundamental itself. This is expressed as:

$$\text{THD} = 20 \log \left[ \frac{\sqrt{(V_2^2 + V_3^2 + V_4^2 + \dots + V_N^2)}}{V_1} \right]$$

where  $V_1$  is the fundamental RMS amplitude, and  $V_2$  to  $V_N$  are the amplitudes of the 2nd through Nth harmonics.

### Spurious-Free Dynamic Range

Spurious-free dynamic range is the ratio of the fundamental RMS amplitude to the amplitude of the next largest spectral component (in the frequency band above DC and below one-half the sample rate). Usually the next largest spectral component occurs at some harmonic of the input frequency. However, if the ADC is exceptionally linear, it may occur only at a random peak in the ADC's noise floor. See "Signal to Noise Ratio" plot in *Typical Operating Characteristics*.

# +3V, 8-Bit ADC with 1 $\mu$ A Power-Down

## Chip Topography

MAX152

TRANSISTOR COUNT: 1856  
SUBSTRATE CONNECTED TO V<sub>DD</sub>

MAX152

## Package Information

MAX152

*+3V, 8-Bit ADC with 1μA Power-Down*

*Package Information (continued)*
